

Tutorials for the R package chngpt

Youyi Fong

March 20, 2018

This tutorial illustrates the use of *chngpt* (Fong et al., 2017a) with code examples. Estimation methods are described in Fong (2018); Fong et al. (2017b), hypothesis testing methods are described in Fong et al. (2015).

1 Continuous threshold regression models

1.1 Threshold linear regression example 1

To estimate a threshold linear regression model with a segmented-type change point for the relationship between *V3_BioV3B* and *NAb_score* in the *MTCT* dataset, we call

```
fit=chngptm (formula.1=V3_BioV3B~1, formula.2=~NAb_score, dat=mtct.2,
  type="segmented", family="gaussian",
  est.method="fastgrid", var.type="bootstrap", save.boot=TRUE)
```

- `formula.2` and `formula.1`: threshold variable and the rest of the model
- `type`: type of threshold model to fit
- `est.method` defaults to *fastgrid* and is recommended
- `var.type`: *bootstrap* method is recommended here
- `save.boot`: saves bootstrap samples for plotting bootstrap distributions

Calling `summary(fit)`, we get

Change point model type: segmented

Coefficients:

	Est	p.value	(lower	upper)
(Intercept)	-22.33152	NA	-30.07675	-14.58628
NAb_score	67.23925	NA	49.98398	84.49452
(NAb_score-chngpt)+	-64.83129	NA	-81.61413	-48.04845

Threshold:

	31.8%	(lower	upper)
	0.4653923	0.4535000	0.4772845

To get an estimate of the slope after threshold, we call

```
est=lincomb(fit.mtct, comb=c(0,1,1), alpha=0.05); print(est)
```

and get

```

          95%          95%
2.40795883 -0.06780353  4.88372120

```

Calling `plot(fit, which=1)` and `plot(fit, which=3)`, we get the two plots on the left-hand side of Figure 1. Changing `est.method` to `smoothapprox` in the model fit led us to the two plots on the right-hand side.

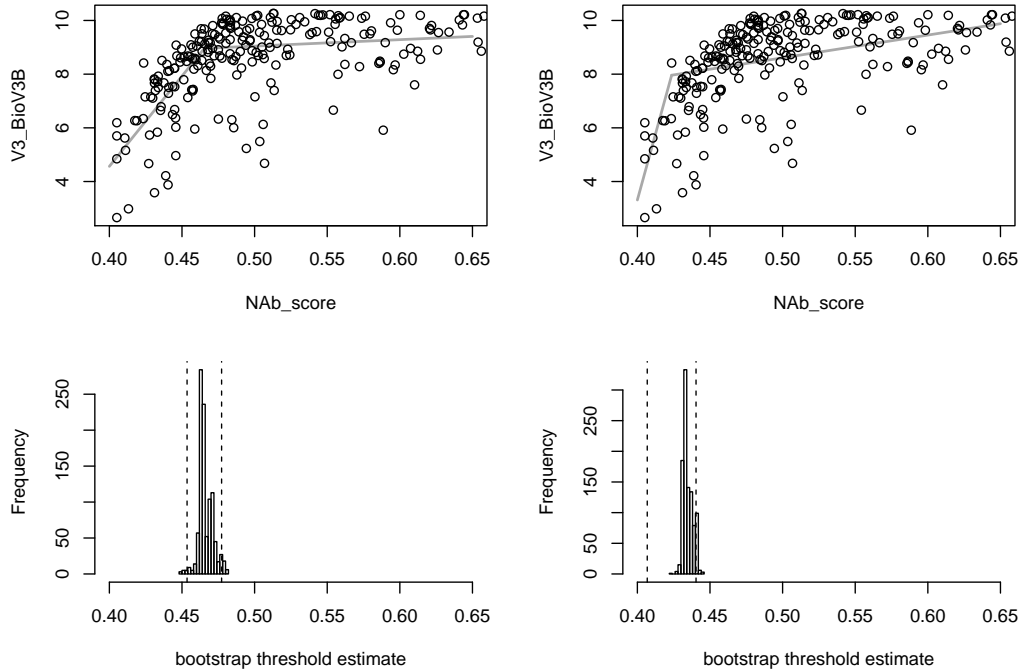

Figure 1: This is a replicate of Fong (2018) Figure 1. Left: results by fast grid search; right: results by smooth approximation search. Top: scatterplots with fitted models (gray lines); bottom: bootstrap distributions of the threshold estimate from 10^3 replicates. The dashed lines correspond to the 95% symmetric bootstrap confidence interval.

1.2 Threshold linear regression example 2

To estimate a threshold linear regression model with a segmented-type change point in *Girth* for the *trees* dataset, we call

```
fit=chngptm(formula.1=Volume~1, formula.2=~Girth, data=trees,  
type="segmented", family="gaussian",  
var.type="bootstrap", weights=NULL)
```

- `formula.2` and `formula.1`: threshold variable and the rest of the model
- `type`: type of threshold model to fit
- `var.type`: *bootstrap* method is recommended for confidence interval
- `weights` can be supplied

Calling `summary(fit)`, we get

Change point model type: segmented

Coefficients:

	Est	p.value	(lower.(Intercept)	upper).(Intercept)
(Intercept)	-24.614440	NA	-37.580354	-11.648527
Girth	3.993966	NA	2.785558	5.202373
(Girth-chngpt)+	4.266618	NA	1.765770	6.767467

Threshold:

74.2% (lower upper)
16.0 12.9 19.1

Calling `plot(fit)`, we get Figure 2.

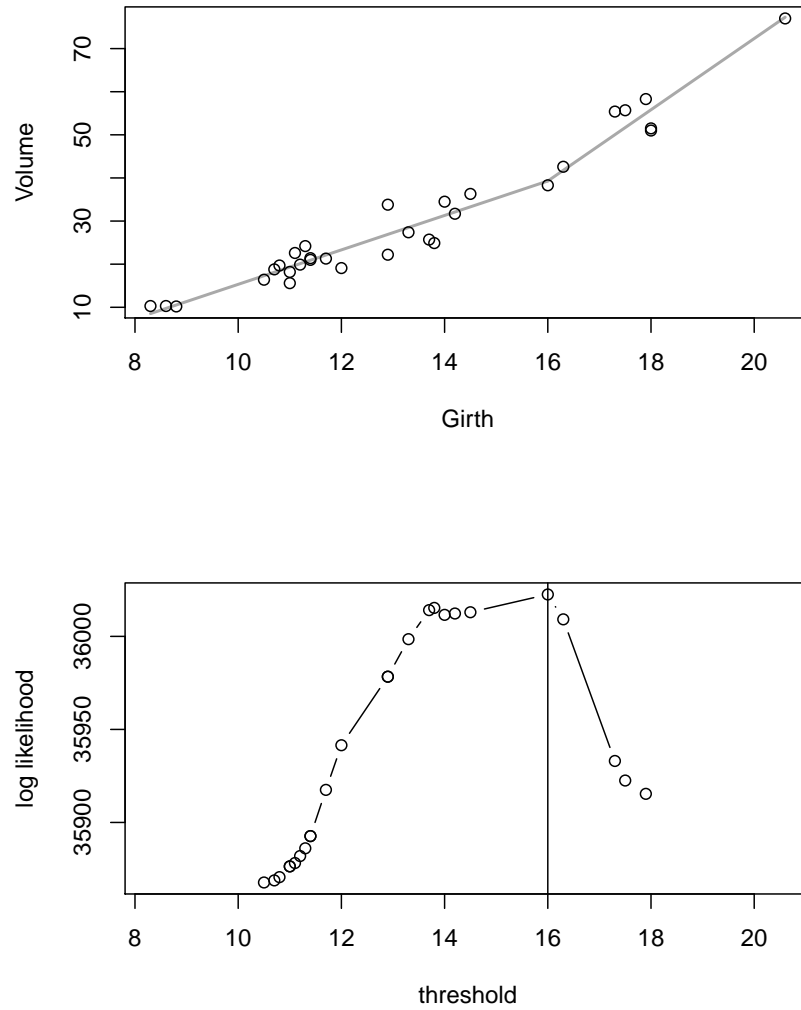

Figure 2: (a) Scatterplot of timber volume vs girth. The gray line shows the fitted segmented model. (b) Log likelihood of the submodel versus threshold parameter.

To test whether there is a change point, we call

```
test=chngpt.test(formula.null=Volume~1, formula.chngpt=~Girth, trees,  
type="segmented", family="gaussian")
```

When printed, we get

Maximum of Likelihood Ratio Statistics

```
data: trees
```

```
Maximal statistic = 17.694, change point = 15.388, p-value = 0.00014
```

```
alternative hypothesis: two-sided
```

The first line gives the type of test carried out, and it is maximal likelihood ratio test here, which is the default. In addition, a plot function can be called on the test object to show the score or likelihood ratio statistic as a function of candidate change points.

1.3 Threshold logistic regression example 1

To estimate a logistic regression model with a hinge-type change point in *NAb_SF162L* for the MTCT dataset, we call

```
library(splines)
fit=chngptm(formula.1=y~birth, formula.2=~NAb_SF162LS, dat.mtct,
type="hinge", family="binomial",
est.method="smoothapprox", var.type="robust",
aux.fit=glm(y~birth + ns(NAb_SF162LS,3), dat.mtct, family="binomial"))
```

- `formula.2` and `formula.1`: threshold variable and the rest of the model
- `type`: type of threshold model to fit
- `est.method`: *smoothapprox* is recommended
- `var.type`: *robust* is recommended for confidence interval
- `aux.fit`: required for *robust* variance estimation

Calling `summary(fit)`, we get

Change point model type: hinge

Coefficients:

	OR	p.value	(lower	upper)
(Intercept)	0.7026523	0.341429662	0.3388366	1.4571044
birthVaginal	1.2397649	0.523159883	0.6393632	2.4039809
(NAb_SF162LS-chngpt)+	0.6712371	0.001332547	0.5270730	0.8548327

Threshold:

26.3%	(lower	upper)
7.373374	5.472271	8.186464

To test whether there is a change point, we call

```
test=chngpt.test(formula.null=y~birth, formula.chngpt=~NAb_SF162LS, dat.mtct,
type="hinge", family="binomial", main.method="score")
```

When printed, we get

Maximum of Score Statistics

data: dat.mtct

Maximal statistic = 3.3209, change point = 7.0347, p-value = 0.00284

alternative hypothesis: two-sided

The first line gives the type of test carried out, and it may be maximal likelihood ratio test. In addition, a plot function can be called on the test object to show the score or likelihood ratio statistic as a function of candidate change points.

2 Discontinuous threshold regression models

The package also provides some support for estimation and hypothesis testing under discontinuous threshold regression models. What is missing, though, is confidence intervals for parameter estimates.
